

## Assignment 2: Scanner and Symbol Table

(Posted on 4/12, Due 5/3 23:59PM)

In this assignment, you are required to write a C-- scanner (The language C-- has been posted on the class website) using the Lex/Flex tool. You are also required to use basic symbol table manipulation routines (lookup(), insertID() and printSymTab()) provided to handle all identifiers. Tokens to be scanned by your scanner are all valid symbols that you would expect to see in a C-- program. There are five classes of tokens to handle: operators, separators, identifiers, reserved words and constants (See the C-- specification for the 5 classes of tokens). Comments are considered as white spaces, and should be stripped off. However, in this assignment, you should define comments as a token, just to exercise your RE writing skills. The rules for token definitions can be derived from the description of the C-- language. Although your scanner should be designed to work with your parser (will be implemented in assignment#3), in this assignment, your scanner only needs to handle the following jobs:

- Print each comment captured by your token RE (regular expression).
- Print the frequency of each identifier

An example program is shown below along with the results that your scanner is expected to print out.

```
=====program start=====
int main()
{
/* 1: this is * just a / sample */
int n;
int abc, def, main_1;
int a1;
float b1, z_123_x_45;
write("Enter a number");

/* 2: this is a 3-line
      comment
*/
n = read();
abc = n + 1;
def = abc * abc;
write(def); /* 3: this is /* the end ***/
}
=====program end=====
```

The output from your scanner looks like the following:

```
/* 1: this is * just a / sample */
/* 2: this is a 3-line
      comment
*/
/* 3: this is /* the end ***/
```

Frequency of identifiers:  
a1 1

abc	4
b1	1
def	3
main	1
main_1	1
n	3
read	1
write	2
z_123_x_45	1

Note:

- a) It is required that the outputs be sorted. You could simply use the strcmp library function to do the sorting. In this assignment, the entire " (double quote) delimited string is treated as a single token i.e. a string constant. In the case of some unknown tokens, your scanner should issue an error message, and print out the unrecognized token, then exit.
- b) You may assume the identifier names will not exceed 256 characters. However, the number of distinct identifiers should not be limited.
- c) In the hw2 directory you may find the following files:
  - 1) src/lexer.l                      the lex template code that you may start with
  - 2) src/symboltable.c            contains symbol table manipulation routines
  - 3) src/header.h                  contains a sample symbol table structure
  - 4) src/Makefile
  - 5) test/                            a test directory containing some sample tests
  - 6) tar.sh                          package script

### Submission requirements:

- 1) DO NOT change the executable name (scanner).
- 2) Use the script file "tar.sh" to package your assignment into a single file. Then upload your packaged assignment to Ceiba.

Usage: ./tar.sh source\_directory studentID version\_number

Example: ./tar.sh hw1 r08921059 ver1

Output: r08921059\_ver1.tar.bz2 (submit this file)

- 3) We grade the assignments on linux.

TAs' email addresses are as follows:

r08921059@ntu.edu.tw

If you need to make changes to your submitted files, you may submit a new version before the deadline.
